

# Hackathon Problem Statement: Django Basic Project

---

You are building a simple Django web application to **calculate the Net Salary of an Employee** based on user input. The application should take **employee details via an HTML form**, compute the **net salary**, and display a summary on a result page.

## Functional Requirements

1. Create a view that renders a form using **plain HTML** (not Django Forms).
2. Accept the following fields as input:
  - o Employee Name
  - o Age
  - o Company
  - o Gross Salary
  - o Tax
  - o Bonus
3. When the form is submitted (via POST):
  - o Calculate **Net Salary** using the formula:
  - o Display the **Employee Name** and the **Net Salary** on a result page.

Tax and bonus are in percentages

4. Also, in a separate URL, input a word from the user and display the jumbled version of the word in the same page
